

GALAHAD

PSLS

USER DOCUMENTATION

GALAHAD Optimization Library version 5.0

1 SUMMARY

Given a sparse symmetric matrix $\mathbf{A} = \{a_{ij}\}_{n \times n}$, this package **builds a suitable symmetric, positive definite—or diagonally dominant—preconditioner \mathbf{P} of \mathbf{A}** or a symmetric sub-matrix thereof. The matrix \mathbf{A} need not be definite. Facilities are provided to apply the preconditioner to a given vector, and to remove rows and columns (symmetrically) from the initial preconditioner without a full re-factorization.

ATTRIBUTES — Versions: GALAHAD_PSLs_single, GALAHAD_PSLs_double. **Calls:** GALAHAD_CLOCK, GALAHAD_SYMBOLS, GALAHAD_SPACE, GALAHAD_SORT, GALAHAD_SPECFILE, GALAHAD_SMT, GALAHAD_QPT, GALAHAD_SLS, GALAHAD_SCU, GALAHAD_EXTEND, GALAHAD_NORMS, LANCELOT_BAND and optionally MC61, HSL_MI28 and ICFS, **Date:** April 2008. **Origin:** N. I. M. Gould, Rutherford Appleton Laboratory. **Language:** Fortran 95 + TR 15581 or Fortran 2003. **Parallelism:** GALAHAD_SLS may use OpenMP, MPI and their runtime libraries.

2 HOW TO USE THE PACKAGE

2.1 Calling sequences

The package is available using both single and double precision reals, and either 32-bit or 64-bit integers. Access to the 32-bit integer, single precision version requires the USE statement

```
USE GALAHAD_PSLs_single
```

with the obvious substitution GALAHAD_PSLs_double, GALAHAD_PSLs_single_64 and GALAHAD_PSLs_double_64 for the other variants.

If it is required to use more than one of the modules at the same time, the derived types SMT_type, PSLS_control_type, PSLS_time_type, PSLS_data_type, and PSLS_inform_type (§2.6), and the subroutines PSLS_initialize, PSLS_form_and_factorize, PSLS_update_factors, PSLS_apply, PSLS_terminate (§2.7), must be renamed on one of the USE statements.

There are five principal subroutines for user calls (see §2.9 for further features):

PSLS_initialize must be called to set default values for solver-specific components of the control structure. If non-default values are wanted for any of the control components, the corresponding components should be altered after the call to PSLS_initialize.

PSLS_form_and_factorize accepts the pattern of \mathbf{A} , removes any unwanted rows and columns, sets up necessary data structures and then forms and factorizes the required preconditioner, \mathbf{P} .

PSLS_update_factors modifies the preconditioner and its factorization if further rows and columns are removed.

PSLS_apply uses the factors generated by PSLS_factorize to solve a system of equations $\mathbf{P}\mathbf{x} = \mathbf{b}$.

PSLS_terminate deallocates the arrays held inside the structure for the factors. It should be called when all the systems involving its matrix have been solved or before another external solver is to be used.

All use is subject to the conditions of a BSD-3-Clause License.

See <http://galahad.rl.ac.uk/galahad-www/cou.html> for full details.

solver	factorization	indefinite \mathbf{A}	out-of-core	parallelised
SILS/MA27	multifrontal	yes	no	no

POTR	dense	no	no	with parallel LAPACK
SYTR	dense	yes	no	with parallel LAPACK
PBTR	dense band	no	no	with parallel LAPACK

Table 2.1: External solver characteristics.

2.2 Supported external solvers

In Table 2.1 we summarize key features of the external solvers supported by PSLs, and used by some preconditioning options. Further details are provided in the references cited in §4 of the documentation to the GALAHAD package SLS. Note that many of the solvers **are not part of the package, and must be obtained separately**.

2.3 Matrix storage formats

The matrix \mathbf{A} may be stored in a variety of input formats.

2.3.1 Sparse co-ordinate storage format

Only the nonzero entries of the lower-triangular part of \mathbf{A} are stored. For the l -th entry of the lower-triangular portion of \mathbf{A} , its row index i , column index j and value a_{ij} are stored in the l -th components of the integer arrays `row`, `col` and real array `val`, respectively. The order is unimportant, but the total number of entries `ne` is also required.

2.3.2 Sparse row-wise storage format

Again only the nonzero entries of the lower-triangular part are stored, but this time they are ordered so that those in row i appear directly before those in row $i + 1$. For the i -th row of \mathbf{A} , the i -th component of an integer array `ptr` holds the position of the first entry in this row, while `ptr(m + 1)` holds the total number of entries plus one. The column indices j and values a_{ij} of the entries in the i -th row are stored in components $l = \text{ptr}(i), \dots, \text{ptr}(i + 1) - 1$ of the integer array `col`, and real array `val`, respectively.

For sparse matrices, this scheme almost always requires less storage than its predecessor.

2.3.3 Dense storage format

The matrix \mathbf{A} is stored as a compact dense matrix by rows, that is, the values of the entries of each row in turn are stored in order within an appropriate real one-dimensional array. Since \mathbf{A} is symmetric, only the lower triangular part (that is the part a_{ij} for $1 \leq j \leq i \leq n$) need be held, and this part will be stored by rows, that is component $i * (i - 1) / 2 + j$ of the storage array `val` will hold the value a_{ij} (and, by symmetry, a_{ji}) for $1 \leq j \leq i \leq n$.

All use is subject to the conditions of a BSD-3-Clause License.

See <http://galahad.rl.ac.uk/galahad-www/cou.html> for full details.

2.4 Real and integer kinds

We use the terms integer and real to refer to the fortran keywords `REAL(rp_)` and `INTEGER(ip_)`, where `rp_` and `ip_` are the relevant kind values for the real and integer types employed by the particular module in use. The former are equivalent to default `REAL` for the single precision versions and `DOUBLE PRECISION` for the double precision cases, and correspond to `rp_ = real32` and `rp_ = real64`, respectively, as supplied by the fortran `iso_fortran_env` module. The latter are default (32-bit) and long (64-bit) integers, and correspond to `ip_ = int32` and `ip_ = int64`, respectively, again from the `iso_fortran_env` module.

2.5 Parallel usage

OpenMP may be used by the `GALAHAD_PSLs` package to provide parallelism for some solvers in shared memory environments. See the documentation for the `GALAHAD` package `SLS` for more details. To run in parallel, OpenMP must be enabled at compilation time by using the correct compiler flag (usually some variant of `-openmp`). The number of threads may be controlled at runtime by setting the environment variable `OMP_NUM_THREADS`.

MPI may also be used by the package to provide parallelism for some solvers in a distributed memory environment. To use this form of parallelism, MPI must be enabled at runtime by using the correct compiler flag (usually some variant of `-lmpi`). Although the MPI process will be started automatically when required, it should be stopped by the calling program once no further use of this form of parallelism is needed. Typically, this will be via statements of the form

```
CALL MPI_INITIALIZED( flag, ierr )
IF ( flag ) CALL MPI_FINALIZE( ierr )
```

The code may be compiled and run in serial mode.

2.6 The derived data types

Five derived data types are used by the package.

2.6.1 The derived data type for holding the matrix

The derived data type `SMT_type` is used to hold the matrix **A**. The components of `SMT_type` used are:

`n` is a scalar variable of type `INTEGER(ip_)`, that holds the order n of the matrix **A**. **Restriction:** $n \geq 1$.

`type` is an allocatable array of rank one and type default `CHARACTER`, that indicates the storage scheme used. If the sparse co-ordinate scheme (see §2.3.1) is used the first ten components of `type` must contain the string `COORDINATE`. For the sparse row-wise storage scheme (see §2.3.2), the first fourteen components of `type` must contain the string `SPARSE_BY_ROWS`, and for dense storage scheme (see §2.3.3) the first five components of `type` must contain the string `DENSE`.

For convenience, the procedure `SMT_put` may be used to allocate sufficient space and insert the required keyword into `type`. For example, if **A** is to be stored in the structure `A` of derived type `SMT_type` and we wish to use the co-ordinate scheme, we may simply

```
CALL SMT_put( A%type, 'COORDINATE', istat )
```

See the documentation for the `GALAHAD` package `SMT` for further details on the use of `SMT_put`.

`ne` is a scalar variable of type `INTEGER(ip_)`, that holds the number of entries in the **lower triangular** part of **A** in the sparse co-ordinate storage scheme (see §2.3.1). It need not be set for any of the other three schemes.

All use is subject to the conditions of a BSD-3-Clause License.

See <http://galahad.rl.ac.uk/galahad-www/cou.html> for full details.

- `val` is a rank-one allocatable array of type `REAL(rp_)`, that holds the values of the entries of the **lower triangular** part of the matrix **A** for each of the storage schemes discussed in §2.3. Any duplicated entries that appear in the sparse co-ordinate or row-wise schemes will be summed.
- `row` is a rank-one allocatable array of type `INTEGER(ip_)`, that holds the row indices of the **lower triangular** part of **A** in the sparse co-ordinate storage scheme (see §2.3.1). It need not be allocated for any of the other schemes. Any entry whose row index lies out of the range $[1,n]$ will be ignored.
- `col` is a rank-one allocatable array variable of type `INTEGER(ip_)`, that holds the column indices of the **lower triangular** part of **A** in either the sparse co-ordinate (see §2.3.1), or the sparse row-wise (see §2.3.2) storage scheme. It need not be allocated when the dense storage scheme is used. Any entry whose column index lies out of the range $[1,n]$ will be ignored, while the row and column indices of any entry from the **strict upper triangle** will implicitly be swapped.
- `ptr` is a rank-one allocatable array of size $n+1$ and type `INTEGER(ip_)`, that holds the starting position of each row of the **lower triangular** part of **A**, as well as the total number of entries plus one, in the sparse row-wise storage scheme (see §2.3.2). It need not be allocated for the other schemes.

2.6.2 The derived data type for holding control parameters

The derived data type `PSLS_control_type` is used to hold controlling data. Default values specifically for the desired solver may be obtained by calling `PSLS_initialize` (see §2.7.1), while components may be changed at run time by calling `PSLS_read_specfile` (see §2.9.1). The components of `PSLS_control_type` are:

- `error` is a scalar variable of type `INTEGER(ip_)`, that holds the unit number for error messages. Printing of error messages is suppressed if `error < 0`. The default is `error = 6`.
- `out` is a scalar variable of type `INTEGER(ip_)`, that holds the unit number for informational messages. Printing of informational messages is suppressed if `out < 0`. The default is `out = 6`.
- `print_level` is a scalar variable of type `INTEGER(ip_)`, that is used to control the amount of informational output that is required. No informational output will occur if `print_level ≤ 0`. Every increasing values produce more information. The default is `print_level = 0`.
- `preconditioner` is a scalar variable of type `INTEGER(ip_)`, that indicates the preconditioner required. Possible values are
- <0 no preconditioning occurs, $\mathbf{P} = \mathbf{I}$
 - 0 the preconditioner is chosen automatically (forthcoming, and currently defaults to 1).
 - 1 **A** is replaced by the diagonal, $\mathbf{P} = \text{diag}(\max(\mathbf{A}, \text{min_diagonal}))$ (see below).
 - 2 **A** is replaced by the band $\mathbf{P} = \text{band}(\mathbf{A})$ with semi-bandwidth `semi_bandwidth` (see below).
 - 3 **A** is replaced by the reordered band $\mathbf{P} = \text{band}(\text{order}(\mathbf{A}))$ with semi-bandwidth `semi_bandwidth`, where `order` is chosen by the HSL package `MC61` (see §4) to move entries closer to the diagonal.
 - 4 **P** is a full factorization of **A** using Schnabel-Eskow modifications, in which small or negative diagonals are made sensibly positive during the factorization.
 - 5 **P** is a full factorization of **A** due to Gill, Murray, Ponceléon and Saunders, in which an indefinite factorization is altered to give a positive definite one.
 - 6 **P** is an incomplete Cholesky factorization of **A** using the package `ICFS` due to Lin and Moré (see §4).
 - 7 **P** is an incomplete factorization of **A** implemented as `HSL_MI28` from HSL (see §4).
 - 8 **P** is an incomplete factorization of **A** due to Munsgaard (forthcoming).

All use is subject to the conditions of a BSD-3-Clause License.

See <http://galahad.rl.ac.uk/galahad-www/cou.html> for full details.

>8 treated as 0.

N.B. Options 3–8 may require additional external software that is not part of the package, and that must be obtained separately. The default is `preconditioner = 0`.

`semi_bandwidth` is a scalar variable of type `INTEGER(ip_)`, that holds the semi-bandwidth used if a band preconditioner (`%preconditioner = 2,3`) is selected. Any negative value will be regarded as 0. The default is `semi_bandwidth = 5`.

`max_col` is a scalar variable of type `INTEGER(ip_)`, that holds the maximum number of nonzeros in a column of **A** that are allowed for a Schur-complement factorization, rather than a refactorization, to accommodate newly deleted columns. The default is `max_col = 100`.

`icfs_vectors` is a scalar variable of type `INTEGER(ip_)`, that holds the number of extra vectors of length n required by the Lin–Moré incomplete Cholesky preconditioner (`%preconditioner = 6`). Usually, the larger the number, the better the preconditioner, but the more space and effort required to use it. Any negative value will be regarded as 0. The default is `icfs_vectors = 10`.

`mi28_lsize` is a scalar variable of type `INTEGER(ip_)`, that holds the maximum number of fill entries within each column of the incomplete factor **L** computed by `HSL_MI28` (`%preconditioner = 7`). In general, increasing `mi28_lsize` improves the quality of the preconditioner but increases the time to compute and then apply the preconditioner. Values less than 0 are treated as 0. The default is `mi28_lsize = 10`.

`mi28_rsize` is a scalar variable of type `INTEGER(ip_)`, that holds the maximum number of entries within each column of the strictly lower triangular matrix **R** used in the computation of the preconditioner by `HSL_MI28` (`%preconditioner = 7`). Rank-1 arrays of size `mi28_rsize` times n are allocated internally to hold **R**. Thus the amount of memory used, as well as the amount of work involved in computing the preconditioner, depends on `mi28_rsize`. Setting `mi28_rsize > 0` generally leads to a higher quality preconditioner than using `mi28_rsize = 0`, and choosing `mi28_rsize ≥ mi28_lsize` is generally recommended. The default is `mi28_rsize = 10`.

`max_col` is a scalar variable of type `INTEGER(ip_)`, that specifies Any non-positive value will be regarded as 1. The default is `max_col = 100`.

`prefix` is a scalar variable of type `default CHARACTER` and length 30, that may be used to provide a user-selected character string to preface every line of printed output. Specifically, each line of output will be prefaced by the string `prefix(2:LEN(TRIM(prefix))-1)`, thus ignoring the first and last non-null components of the supplied string. If the user does not want to preface lines by such a string, the default `prefix = ""` should be used.

`min_diagonal` is a scalar variable of type `REAL(rp_)`, that specifies the smallest permitted diagonal in **P** for some of the preconditioners provided. See `preconditioner` above. The default is `min_diagonal = 0.00001`.

`new_structure` is a scalar variable of type `default LOGICAL`, that must be set `.TRUE.` if the storage structure for the input matrix has changed, and `.FALSE.` if only the values have changed. The default is `new_structure = .TRUE..`

`get_semi_bandwidth` is a scalar variable of type `default LOGICAL`, that must be set `.TRUE.` if the user wishes the package to calculate the semi-bandwidth of the preconditioner, **P** and `.FALSE.` otherwise. The default is `get_semi_bandwidth = .TRUE..`

`get_norm_residual` is a scalar variable of type `default LOGICAL`, that must be set `.TRUE.` if the user wishes the package to return the value of the norm of the residuals for the computed solution when applying the preconditioner and `.FALSE.` otherwise. The default is `get_norm_residual = .FALSE..`

`space_critical` is a scalar variable of type `default LOGICAL`, that must be set `.TRUE.` if space is critical when allocating arrays and `.FALSE.` otherwise. The package may run faster if `space_critical` is `.FALSE.` but at the possible expense of a larger storage requirement. The default is `space_critical = .FALSE..`

All use is subject to the conditions of a BSD-3-Clause License.

See <http://galahad.rl.ac.uk/galahad-www/cou.html> for full details.

`deallocate_error_fatal` is a scalar variable of type default LOGICAL, that must be set `.TRUE.` if the user wishes to terminate execution if a deallocation fails, and `.FALSE.` if an attempt to continue will be made. The default is `deallocate_error_fatal = .FALSE..`

`definite_linear_solver` is a scalar variable of type default CHARACTER and length 30, that specifies the external package to be used to solve any symmetric positive-definite linear system that might arise when `%preconditioner = 4,5`. Possible choices are `'sils'`, `'ma27'`, `'ma57'`, `'ma77'`, `'ma86'`, `'ma87'`, `'ma97'`, `'ssids'`, `'pardiso'`, `'mkl_pardiso'`, `'wsmp'`, `'potr'` and `'pbtr'`, although only `'sils'`, `'potr'`, `'pbtr'` and, for OMP 4.0-compliant compilers, `'ssids'` are installed by default. See Table 2.1 and the documentation for the GALAHAD package SLS for further details. The default is `definite_linear_solver = 'sils'`.

`prefix` is a scalar variable of type default CHARACTER and length 30, that may be used to provide a user-selected character string to preface every line of printed output. Specifically, each line of output will be prefaced by the string `prefix(2:LEN(TRIM(prefix))-1)`, thus ignoring the first and last non-null components of the supplied string. If the user does not want to preface lines by such a string, they may use the default `prefix = ""`.

2.6.3 The derived data type for holding timing information

The derived data type `PSLS_time_type` is used to hold elapsed CPU and system clock times for the various parts of the calculation. The components of `PSLS_time_type` are:

`total` is a scalar variable of type `REAL(rp_)`, that gives the total CPU time (in seconds) spent in the package.

`analyse` is a scalar variable of type `REAL(rp_)`, that gives the CPU time spent analysing the matrix structure prior to building and factorizing the preconditioner.

`factorize` is a scalar variable of type `REAL(rp_)`, that gives the CPU time spent building and factorizing the preconditioner.

`solve` is a scalar variable of type `REAL(rp_)`, that gives the CPU time spent applying the preconditioner.

`update` is a scalar variable of type `REAL(rp_)`, that gives the CPU time spent updating existing factorizations.

`clock_total` is a scalar variable of type `REAL(rp_)`, that gives the total elapsed system clock time (in seconds) spent in the package.

`clock_analyse` is a scalar variable of type `REAL(rp_)`, that gives the elapsed system clock time spent analysing the matrix structure prior to building and factorizing the preconditioner.

`clock_factorize` is a scalar variable of type `REAL(rp_)`, that gives the elapsed system clock time spent building and factorizing the preconditioner.

`clock_solve` is a scalar variable of type `REAL(rp_)`, that gives the elapsed system clock time spent applying the preconditioner.

`clock_update` is a scalar variable of type `REAL(rp_)`, that gives the elapsed system clock time spent updating existing factorizations.

2.6.4 The derived data type for holding informational parameters

The derived data type `PSLS_inform_type` is used to hold parameters that give information about the progress and needs of the algorithm. The components of `PSLS_inform_type` are as follows—any component that is not relevant to the solver being used will have the value `-1` or `-1.0` as appropriate:

`status` is a scalar variable of type `INTEGER(ip_)`, that gives the exit status of the algorithm. See §2.8 for details.

All use is subject to the conditions of a BSD-3-Clause License.

See <http://galahad.rl.ac.uk/galahad-www/cou.html> for full details.

`alloc_status` is a scalar variable of type `INTEGER(ip_)`, that gives the status of the last attempted array allocation or deallocation.

`bad_alloc` is a scalar variable of type default `CHARACTER` and length 80, that gives the name of the last internal array for which there were allocation or deallocation errors. This will be the null string if there have been no allocation or deallocation errors.

`preconditioner` is a scalar variable of type `INTEGER(ip_)`, that indicates the preconditioner method used. The range of values returned corresponds to those requested in `control%preconditioner`, excepting that the requested value may have been altered to a more appropriate one during the factorization. In particular, if the automatic choice `control%preconditioner = 0` is requested, `preconditioner` reports the actual choice made.

`semi_bandwidth` is a scalar variable of type `INTEGER(ip_)`, that indicates the actual semi-bandwidth.

`reordered_semi_bandwidth` is a scalar variable of type `INTEGER(ip_)`, that indicates the semi-bandwidth used after reordering.

`semi_bandwidth_used` is a scalar variable of type `INTEGER(ip_)`, that indicates the actual semi-bandwidth used.

`out_of_range` is a scalar variable of type `INTEGER(ip_)`, that is set to the number of entries of **A** supplied with one or both indices out of range.

`duplicates` is a scalar variable of type `INTEGER(ip_)`, that is set to the number of duplicate off-diagonal entries of **A** supplied.

`upper` is a scalar variable of type `INTEGER(ip_)`, that is set to the number of input entries from the strict upper triangle of **A**.

`missing_diagonals` is a scalar variable of type `INTEGER(ip_)`, that gives the number of diagonal entries missing for an allegedly-definite matrix **A**.

`neg1` is a scalar variable of type `INTEGER(ip_)`, that gives the number of 1 by 1 pivots present in the factorization of **A**.

`neg2` is a scalar variable of type `INTEGER(ip_)`, that gives the number of 2 by 2 pivots present in the factorization of **A**.

`perturbed` is a scalar variable of type default `LOGICAL`, that is `/true/` if the factorization has been perturbed when building the preconditioner.

`fill_in_ratio` is a scalar variable of type `REAL(rp_)`, that gives the ratio of the fill-ins during factorization to the original numbers of non-zeros of **A**.

`norm_residual` is a scalar variable of type `REAL(rp_)`, that gives the norm of the residual $\|\mathbf{P}\mathbf{x} - \mathbf{b}\|$ when solving $\mathbf{P}\mathbf{x} = \mathbf{b}$.

`mc61_info` is an array of size 10 and type `INTEGER(ip_)`, that corresponds to the output array `INFO` from MC61. See the HSL documentation for MC61 for further details.

`mc61_rinfo` is an array of size 15 and type `REAL(rp_)`, that corresponds to the output array `RINFO` from MC61. See the HSL documentation for MC61 for further details.

`time` is a scalar variable of type `PSLS_time_type` whose components are used to hold elapsed CPU and system clock times (in seconds) for the various parts of the calculation (see Section 2.6.3).

`sls_inform` is a scalar variable of type `sls_inform_type`, that corresponds to the output value `sls_inform` from the GALAHAD package SLS. See the documentation for SLS for further details.

`mi28_info` is a scalar variable of type `mi28_info`, that corresponds to the output value `mi28_info` from HSL_MI28. See the documentation for HSL_MI28 for further details.

All use is subject to the conditions of a BSD-3-Clause License.
See <http://galahad.rl.ac.uk/galahad-www/cou.html> for full details.

2.6.5 The derived data type for holding problem data

The derived data type `PSLS_data_type` is used to hold all the data for a particular problem, or sequences of problems with the same structure, between calls to PSLs procedures. All components are private.

2.7 Argument lists and calling sequences

We use square brackets [] to indicate OPTIONAL arguments.

2.7.1 The initialization subroutine

The initialization subroutine must be called for each solver used to initialize data and solver-specific control parameters.

```
CALL PSLs_initialize( data, control, inform )
```

`data` is a scalar INTENT (OUT) argument of type `PSLS_data_type` (see §2.6.5). It is used to hold data about the problem being solved.

`control` is a scalar INTENT (OUT) argument of type `PSLS_control_type` (see §2.6.2). On exit, `control` contains solver-specific default values for the components as described in §2.6.2. These values should only be changed after calling `PSLS_initialize`.

`inform` is a scalar INTENT (OUT) argument of type `PSLS_inform_type` (see §2.6.4). A successful call is indicated when the component `status` has the value 0. For other return values of `status`, see §2.8.

2.7.2 The subroutine for constructing the preconditioner

This subroutine assembles and factorizes the required preconditioner from the input matrix **A** as follows:

```
CALL PSLs_form_and_factorize( matrix, data, control, inform[, SUB] )
```

`matrix` is scalar INTENT (IN) argument of type `SMT_type` that is used to specify **A**. The user must set all of the relevant components of `matrix` according to the storage scheme desired (see §2.6.1). Incorrectly-set components will result in errors flagged in `inform%status`, see §2.8.

`data` is a scalar INTENT (INOUT) argument of type `PSLS_data_type` (see §2.6.5). It is used to hold the factors of the preconditioner and other data concerning the matrix used. It must have been initialized by a call to `PSLS_initialize`.

`control` is scalar INTENT (IN) argument of type `PSLS_control_type`. Its components control the action of the analysis phase, as explained in §2.6.2.

`inform` is a scalar INTENT (INOUT) argument of type `PSLS_inform_type` (see §2.6.4). A successful call is indicated when the component `status` has the value 0. For other return values of `status`, see §2.8.

`SUB` is an OPTIONAL INTENT (IN) rank-one default assumed-size INTEGER (`ip_`) argument that may be used to provide a set of distinct indices that specify the rows (and, by symmetry, columns) of **A** that are to be considered. Each component of `SUB` must lie between 1 and n , and they should be input in increasing order. If `SUB` is not supplied, all indices $1 \leq i \leq n$ will be used.

All use is subject to the conditions of a BSD-3-Clause License.

See <http://galahad.rl.ac.uk/galahad-www/cou.html> for full details.

2.7.3 The subroutine for updating the preconditioner

This subroutine updates the factorization of the preconditioner when a subset of the rows (and, by symmetry, columns) are removed.

```
CALL PSLUpdate_factors( DEL, data, control, inform )
```

`DEL` is an `INTENT(IN)` rank-one default assumed-size `INTEGER(ip_)` argument whose indices are those of rows (and columns) of \mathbf{A} that are to be deleted. Each component of `DEL` must lie between 1 and n .

`data` is a scalar `INTENT(INOUT)` argument of type `PSLS_data_type` (see §2.6.5). It is used to hold the factors of the updated preconditioner and other data concerning the matrix used. It must have been previously set by a call to `PSLS_form_and_factorize`.

`control` is scalar `INTENT(IN)` argument of type `PSLS_control_type`. Its components control the action of the analysis phase, as explained in §2.6.2.

`inform` is a scalar `INTENT(INOUT)` argument of type `PSLS_inform_type` (see §2.6.4). A successful call is indicated when the component `status` has the value 0. For other return values of `status`, see §2.8.

2.7.4 The subroutine for applying the preconditioner

Given the preconditioner \mathbf{P} , a set of equations $\mathbf{P}\mathbf{x} = \mathbf{b}$ may be solved as follows:

```
CALL PSLApply( X, data, control, inform )
```

`X` is an `INTENT(INOUT)` assumed-shape array argument of rank 1 and of type `REAL(rp_)`. On entry, `X` must be set to the vector \mathbf{b} , and on successful return it holds the solution \mathbf{x} . The i -th component of \mathbf{b} and the resulting i -th component of the solution \mathbf{x} occupy the i -th component of `X`. Any component corresponding to rows/columns not in the initial subset recorded by `PSLS_form_and_factorize`, or in those subsequently deleted by `PSLS_update_factors`, will not be altered.

`data` is a scalar `INTENT(INOUT)` argument of type `PSLS_data_type` (see §2.6.5). It is used to hold the factors and other data about the problem being solved. It must have been initialized by a call to `PSLS_initialize` and not altered by the user in the interim.

`control` is scalar `INTENT(IN)` argument of type `PSLS_control_type`. Its components control the action of the solve phase, as explained in §2.6.2.

`inform` is a scalar `INTENT(INOUT)` argument of type `PSLS_inform_type` (see §2.6.4). A successful call is indicated when the component `status` has the value 0. For other return values of `status`, see §2.8.

2.7.5 The termination subroutine

All previously allocated internal arrays are deallocated and OpenMP locks destroyed as follows:

```
CALL PSLTerminate( data, control, inform )
```

`data` is a scalar `INTENT(INOUT)` argument of type `PSLS_data_type` (see §2.6.5). It is used to hold the factors and other data about the problem being solved. It must have been initialized by a call to `PSLS_initialize` and not altered by the user in the interim. On exit, its allocatable array components will have been deallocated.

`control` is scalar `INTENT(IN)` argument of type `PSLS_control_type`. Its components control the action of the termination phase, as explained in §2.6.2.

`inform` is a scalar `INTENT(INOUT)` argument of type `PSLS_inform_type` (see §2.6.4). A successful call is indicated when the component `status` has the value 0. For other return values of `status`, see §2.8.

All use is subject to the conditions of a BSD-3-Clause License.

See <http://galahad.rl.ac.uk/galahad-www/cou.html> for full details.

2.8 Warning and error messages

A negative value of `inform%status` on exit from the subroutines indicates that an error has occurred. No further calls should be made until the error has been corrected. Possible values are:

- 1 An allocation error occurred. A message indicating the offending array is written on unit `control%error`, and the returned allocation status and a string containing the name of the offending array are held in `inform%alloc_status` and `inform%bad_alloc` respectively.
- 2 A deallocation error occurred. A message indicating the offending array is written on unit `control%error` and the returned allocation status and a string containing the name of the offending array are held in `inform%alloc_status` and `inform%bad_alloc` respectively.
- 3 One of the restrictions `matrix%n > 0` or `matrix%ne < 0`, for co-ordinate entry, or requirements that `matrix%type` contain its relevant string 'COORDINATE', 'SPARSE_BY_ROWS' or 'DENSE' has been violated.
- 9 The solver required by SLS reported an error during its analysis phase. See `inform%SLS_inform%status` for more details.
- 10 The solver required by SLS reported an error during its factorization phase. See `inform%SLS_inform%status` for more details.
- 20 The matrix is not positive definite while the solver used expected it to be.
- 26 The requested factorization solver is not available.
- 29 A specified option is not available with this solver.
- 45 The requested preconditioner is not available.
- 80 An error occurred when calling HSL_MI28. See `inform%mi28_info%stat` for more details.

2.9 Further features

In this section, we describe an alternative means of setting control parameters, that is components of the variable `control` of type `PSLS_control_type` (see §2.6.2), by reading an appropriate data specification file using the subroutine `PSLS_read_specfile`. This facility is useful as it allows a user to change PSLs control parameters without editing and recompiling programs that call PSLs.

A specification file, or `specfile`, is a data file containing a number of “specification commands”. Each command occurs on a separate line, and comprises a “keyword”, that is a string (in a close-to-natural language) used to identify a control parameter, and an (optional) “value”, which defines the value to be assigned to the given control parameter. All keywords and values are case insensitive, keywords may be preceded by one or more blanks but values must not contain blanks, and each value must be separated from its keyword by at least one blank. Values must not contain more than 30 characters, and each line of the specification file is limited to 80 characters, including the blanks separating keyword and value.

The portion of the specification file used by `PSLS_read_specfile` must start with a “BEGIN PSLs” command and end with an “END” command. The syntax of the `specfile` is thus defined as follows:

```
( .. lines ignored by PSLs_read_specfile .. )
  BEGIN PSLs
    keyword    value
    .....     .....
    keyword    value
  END
( .. lines ignored by PSLs_read_specfile .. )
```

All use is subject to the conditions of a BSD-3-Clause License.

See <http://galahad.rl.ac.uk/galahad-www/cou.html> for full details.

where keyword and value are two strings separated by (at least) one blank. The “BEGIN PSLS” and “END” delimiter command lines may contain additional (trailing) strings so long as such strings are separated by one or more blanks, so that lines such as

```
BEGIN PSLS SPECIFICATION
```

and

```
END PSLS SPECIFICATION
```

are acceptable. Furthermore, between the “BEGIN PSLS” and “END” delimiters, specification commands may occur in any order. Blank lines and lines whose first non-blank character is ! or * are ignored. The content of a line after a ! or * character is also ignored (as is the ! or * character itself). This provides an easy way to “comment out” some specification commands, or to comment specific values of certain control parameters.

The value of a control parameter may be of three different types, namely integer, character or real. Integer and real values may be expressed in any relevant Fortran integer and floating-point formats (respectively).

The specification file must be open for input when `PSLS_read_specfile` is called, and the associated unit number passed to the routine in `device` (see below). Note that the corresponding file is rewound, which makes it possible to combine the specifications for more than one program/routine. For the same reason, the file is not closed by `PSLS_read_specfile`.

2.9.1 To read control parameters from a specification file

Control parameters may be read from a file as follows:

```
CALL PSLS_read_specfile( control, device )
```

`control` is a scalar `INTENT(INOUT)` argument of type `PSLS_control_type` (see §2.6.2). Default values should have already been set, perhaps by calling `PSLS_initialize`. On exit, individual components of `control` may have been changed according to the commands found in the specfile. Specfile commands and the component (see §2.6.2) of `control` that each affects are given in Table 2.2.

`device` is a scalar `INTENT(IN)` argument of type `INTEGER(ip_)`, that must be set to the unit number on which the specification file has been opened. If `device` is not open, `control` will not be altered and execution will continue, but an error message will be printed on unit `control%error`.

3 GENERAL INFORMATION

Workspace: Provided automatically by the module.

Other modules used directly: GALAHAD_CLOCK, GALAHAD_SYMBOLS, GALAHAD_SPACE_single/double, GALAHAD_SORT_single/double, GALAHAD_SPECFILE_single/double, GALAHAD_SMT_single/double, GALAHAD_QPT_single/double, GALAHAD_SLS_single/double, GALAHAD_SCU_single/double, GALAHAD_EXTEND_single/double, GALAHAD_NORMS_single/double, LANCELOT_BAND_single/double.

Other routines called directly: Optionally MC61, HSL_MI28 and ICFS, plus those called by GALAHAD_SLS.

Input/output: Output is under control of the arguments `control%error`, and `control%out`.

Restrictions: $matrix\%n \geq 1$, $matrix\%ne \geq 0$ if $matrix\%type = 'COORDINATE'$, and $matrix\%type$ is one of 'COORDINATE', 'SPARSE_BY_ROWS' or 'DENSE'.

Portability: ISO Fortran 95 + TR 15581 or Fortran 2003 and optionally OpenMP. The package is thread-safe.

All use is subject to the conditions of a BSD-3-Clause License.

See <http://galahad.rl.ac.uk/galahad-www/cou.html> for full details.

4 METHOD

The basic preconditioners are described in detail in Section 3.3.10 of

A. R. Conn, N. I. M. Gould and Ph. L. Toint (1992). LANCELOT. A fortran package for large-scale nonlinear optimization (release A). Springer Verlag Series in Computational Mathematics 17, Berlin, along with the more modern versions implements in ICFS due to

C.-J. Lin and J. J. Moré (1999). Incomplete Cholesky factorizations with limited memory. SIAM Journal on Scientific Computing **21** 21-45,

and in HSL_MI28 described by

J. A. Scott and M. Tuma (2013). HSL MI28: an efficient and robust limited-memory incomplete Cholesky factorization code. ACM Transactions on Mathematical Software **40(4)** (2014), Article 24.

The factorization methods used by the GALAHAD package SLS in conjunction with some preconditioners are described in the documentation to that package. Orderings to reduce the bandwidth, as implemented in HSL's MC61, are due to

J. K. Reid and J. A. Scott (1999) Ordering symmetric sparse matrices for small profile and wavefront International Journal for Numerical Methods in Engineering **45** 1737-1755.

If a subset of the rows and columns are specified, the remaining rows/columns are removed before processing. Any subsequent removal of rows and columns is achieved using the GALAHAD Schur-complement updating package SCU unless a complete re-factorization is likely more efficient.

5 EXAMPLE OF USE

We illustrate the use of the package on the (indefinite) sparse matrix

$$\begin{pmatrix} 2 & 3 & & & \\ 3 & 4 & & 6 & \\ & 4 & 1 & 5 & \\ & & 5 & & \\ 6 & & & & 1 \end{pmatrix}$$

(Note that this example does not illustrate all the facilities). Then, choosing the solver SILS, we may use the following code to find a tridiagonal (banded, with a semi-bandwidth of 1) preconditioner and apply it to a given vector:

```
PROGRAM PSLX_EXAMPLE ! GALAHAD 4.0 - 2022-01-24 AT 09:15 GMT.
USE GALAHAD_PSLX_double
IMPLICIT NONE
INTEGER, PARAMETER :: wp = KIND( 1.0D+0 )
TYPE ( SMT_type ) :: matrix
TYPE ( PSLX_data_type ) :: data
TYPE ( PSLX_control_type ) control
TYPE ( PSLX_inform_type ) :: inform
INTEGER, PARAMETER :: n = 5
INTEGER, PARAMETER :: ne = 7
REAL ( KIND = wp ) :: X( n )
INTEGER :: s
! allocate and set lower triangle of matrix in co-ordinate form
CALL SMT_put( matrix%type, 'COORDINATE', s )
matrix%n = n ; matrix%ne = ne
ALLOCATE( matrix%val( ne ), matrix%row( ne ), matrix%col( ne ) )
matrix%row = (/ 1, 2, 3, 3, 4, 5, 5 /)
```

All use is subject to the conditions of a BSD-3-Clause License.
See <http://galahad.rl.ac.uk/galahad-www/cou.html> for full details.

```

matrix%col = (/ 1, 1, 2, 3, 3, 2, 5 /)
matrix%val = (/ 2.0_wp, 3.0_wp, 4.0_wp, 1.0_wp, 5.0_wp, 6.0_wp, 1.0_wp /)
! problem setup complete
! specify the solver used by SLS (in this case sils)
CALL PSLs_initialize( data, control, inform )
control%preconditioner = 2 ! band preconditioner
control%semi_bandwidth = 1 ! semi-bandwidth of one
control%definite_linear_solver = 'sils'
! form and factorize the preconditioner, P
CALL PSLs_form_and_factorize( matrix, data, control, inform )
IF ( inform%status < 0 ) THEN
  WRITE( 6, '( A, I0 )' )
  ' Failure of PSLs_form_and_factorize with status = ', inform%status &
  STOP
END IF
! use the factors to solve P x = b, with b input in x
X( : n ) = (/ 8.0_wp, 45.0_wp, 31.0_wp, 15.0_wp, 17.0_wp /)
CALL PSLs_apply( X, data, control, inform )
IF ( inform%status == 0 ) THEN
  WRITE( 6, "( ' PSLs - Preconditioned solution is ', 5F6.2 )" ) X
ELSE
  WRITE( 6, "( ' PSLs - exit status = ', I0 )" ) inform%status
END IF
! clean up
CALL PSLs_terminate( data, control, inform )
DEALLOCATE( matrix%type, matrix%val, matrix%row, matrix%col )
STOP
END PROGRAM PSLs_EXAMPLE

```

This produces the following output:

```
PSLS - Preconditioned solution is -6.03 8.03 -4.66 4.20 17.00
```

The same problem may be solved holding the data in a sparse row-wise storage format by replacing the lines

```

! allocate and set lower triangle of matrix in co-ordinate form
...
! problem setup complete

```

by

```

! allocate and set lower triangle of matrix in spares row form
CALL SMT_put( matrix%type, 'SPARSE_BY_ROWS', s )
matrix%n = n
ALLOCATE( matrix%val( ne ), matrix%col( ne ), matrix%ptr( n + 1 ) )
matrix%ptr = (/ 1, 2, 3, 5, 6, 8 /)
matrix%col = (/ 1, 1, 2, 3, 3, 2, 5 /)
matrix%val = (/ 2.0_wp, 3.0_wp, 4.0_wp, 1.0_wp, 5.0_wp, 6.0_wp, 1.0_wp /)
! problem setup complete

```

or using a dense storage format with the replacement lines

```

! allocate and set lower triangle of matrix in dense form
CALL SMT_put( matrix%type, 'DENSE', s )
matrix%n = n
ALLOCATE( matrix%val( n * ( n + 1 ) / 2 ) )
matrix%val = (/ 2.0_wp, 3.0_wp, 0.0_wp, 0.0_wp, 4.0_wp, 1.0_wp, &

```

All use is subject to the conditions of a BSD-3-Clause License.
See <http://galahad.rl.ac.uk/galahad-www/cou.html> for full details.

```
0.0_wp, 0.0_wp, 5.0_wp, 0.0_wp, 0.0_wp, 6.0_wp,      &  
0.0_wp, 0.0_wp, 1.0_wp /)  
! problem setup complete
```

respectively.

All use is subject to the conditions of a BSD-3-Clause License.
See <http://galahad.rl.ac.uk/galahad-www/cou.html> for full details.
